SCARLET VETCH (*Vicia fulgens*).

Scarlet vetch is an annual legume and in a general way similar to common vetch. It, however, is a much more upright plant, so that it can be harvested as hay more easily. Apparently it is somewhat less hardy than common vetch, but is adapted as a winter crop to western Washington, western Oregon, California, and the Southern States. In all regions where vetches are grown this variety should be tested in comparison with common vetch and hairy vetch. In every way the crop should receive the same treatment as common vetch. The seed is at present somewhat expensive, but it is believed that if a demand arises it can be grown as cheaply as common vetch.
